14 Abstract

Recent work examining the mnemonic effects of Sans Forgetica has yielded discrepant 15 findings. To clarify this discrepancy, the present experiments examined a boundary 16 condition that determines when Sans Forgetica is and and is not beneficial to learning. 17 This boundary condition is knowledge about an upcoming test (high test expectancy) 18 versus not (low test expectancy). This boundary condition was tested across two 19 experiments. In Experiment 1 (pre-registered, N=231), Sans Forgetica eliciated lower 20 judgements of learning and longer study times, but only improved memory on a yes/no 21 recognition test when there was low test expectancy (compared to a high test expectancy group). In Experiment 2 (N=116) using a low testing expectancy cued recall test, we found a similar pattern of results to Experiment 1. Taken together, Sans Forgetica can be a desirable difficulty, but only when testing expectancy is low. However, caution should be taken in interpring these results. Not only was were effect sizes small, but low testing 26 expectancy is not practical. Echocing previous sentiments, students wanting to remember 27 more and forget less should stick to other desirable difficultues shown to enhance memory. 28

31

Surprise! Low Testing Expectancy Moderates the Sans Forgetica Effect

Successful remembering is impacted by innumerable factors. One factor that has 32 been purported to enhance remembering is perceptual disfluency. Interfering with word 33 perception during encoding by blurring (Rosner et al., 2015), inversion (Sungkhasettee et al., 2011), or placing in a atypical fonts (Diemand-Yauman et al., 2011) can enhance 35 explicit memory, a phenomenon dubbed the perceptual interference effect (Nairne, 1988), or more recently, the disfluency effect (Geller et al., 2018). One such perceptual 37 manipulation garnering increased attention is Sans Forgetica. Sans Forgetica is a typeface developed by a team of psychologists, graphic designers, and marketers, consisting of intermittent gaps and black-slanted letters (???). The disfluency evoked by this typeface is pruproted to stave off forgetting and enhance learning. The claims surrounding Sans Forgetica have lead to extensive press coverage from major news outlets (e.g., NPR, Washington Post), and have lead to the development of browser extensions and OS applications that allows users to place content in Sans Forgetica. As the famous astronomer Carl Sagan once said, "Extraordinary claims require extraordinary evidence (Sagan, 1980). There is a growing body of evidence suggesting perceptual disfluency manipulations 46 are simply not desirable for learning (see Xie et al., 2018 for a meta-analysis). Does the same hold true for Sans Forgetica? In two independent studies, Taylor et al. (2020) and 48 Geller et al. (2020) set out to examine whether Sans Forgetica is really desirable for learning. In the first conceptual replication of the Sans Forgetica effect, Taylor et al. (2020) found (in a sample of 882 people across 4 experiments) that while Sans Forgetica was perceived as more disfluent by participants (Experiment 1) there was no evidence that Sans Forgetica yielded a mnemonic boost in cued recall with highly related word pairs (Experiment 2) compared to a fluent typeface (Arial) or when learning simple prose passages (Experiments 3-4). Extending these findings, Geller et al. (2020) conducted three 55 pre-registered experiments (with over 800 participants), and found, similar to Taylor et al.

(2020), Sans Forgetica does not enhance learning for weakly related word pairs
(Experiment 1), a complex prose passage on ground water (Experiment 2), or when the
type of test was changed to a recognition memory test (Experiment 3). Taken together,
across two independent replication attempts, and over a 1000 participants, there is weak
evidence for Sans Forgetica as a desirable difficulty.

Despite these findings, some evidence for the effectiveness of the Sans Forgetica typeface does exist. For instance, Eskenazi and Nix (2020) found that Sans Forgetica can enhance learning. In their study, they had participants learn the spelling and meaning for 15 low-frequency words each presented in the context of two sentences while their eye movements were monitored. During the test phase, orthographic discriminabity (i.e., choosing the correct spelling of a word) and semantic acquisition (i.e., retrieving the definition of a word) were assessed. The authors reported a memory benefit for both orthographic discrimnability and semantics for words presented in Sans Forgetica compared to a normal (Courier) typeface, but only for participants that were good spellers.

The mixed findings reported above suggest mnemonic benefit of Sans Forgetica may
be fickle, with positive effects potentially bounded by specific conditions. Probing into the
design features of Eskenazi and Nix (2020), a critical difference between their study and
Taylor et al. (2020) and Geller et al. (2020) is testing expectancy. Eskenazi and Nix (2020)
did did not tell participants about the upcoming orthographic and semantic tests. Thus,
one common design feature that may moderate whether we see a Sans Forgetica effect is
high testing expectancy.

It is well know that testing expectancy can positively influence memory. Expecting
a test of any kind can lead to enhanced processing of studied material, by either reducing
learners' mind-wandering during studying (Szpunar et al., 2007) or by reducing interference
from previously studied information (Weinstein et al., 2014). In the context of perceptual
disfluency effects, Eitel and Kühl (2016) reasoned that if the disfluency effect arises because

94

of deeper, more effortful, processing, telling participants about a memory test should eliminate the effect. This occurs because testing expectancy countervails the effects of perceptual disfluency by eliciting enhanced processing for both fluent and disfluent stimuli. 85 In contrast, low testing expectancy is less likely to impact processing of individual items, leaving effects of processing difficulty intact. While Eitel and Kühl (2016) found 87 evidence for a general testing expectancy effect (better memory for high vs. low testing 88 expectancy) they not find evidence for a moderated disfluency effect. However, Geller and Still (2018), following up on this, demonstrated in a yes/no recognition memory test that the disfluency effect only occurred under low testing expectancy. Given this, it is possible, 91 then, that Sans Forgetica (a disfluent font) might arise when participants have low test 92 expectancy.

Experiment 1

In Experiment 1 we examined whether the positive effects of Sans Forgetica are 95 moderated by testing expectancy. Using a yes/no recognition memory test, we manipulated 96 testing expectancy by telling half the participants about the upcoming memory test while 97 for the other half being surreptitious about the upcoming memory test. In addition, we collected list-wide judgments of learning (i.e., a subjective memory prediction about future memory performance taken after all items are studied) and study times as a manipulation 100 check to ensure Sans Fagoretica is perceptual disfluent. We preregistered that we would 101 observe an interaction between typeface (Arial vs. Sans Forgetica) and Test Expectancy. 102 Specifically, if participants were not told about a memory test (low test expectancy) we would see a memory boost for Sans Forgetica stimuli, but not if they were told about a memory test. For JOLs, we predicted that we would not see JOL differences as function of 105 typeface or testing expectancy. In terms of reading times, we predicted we would see longer 106 study times for Sans Forgetica, but only in the low testing expectancy condition. These 107 predictions are based on Geller et al. (2020) (Experiments 2 and 3). 108

$_{109}$ Method

The preregistered analysis plan for Experiment 1 can be found here:
https://osf.io/wgp9d. All raw and summary data, materials, and R scripts for
pre-processing, analysis, and plotting can be found at https://osf.io/d2vy8/.

113 Participants

We preregistered a sample size of 230. All participants were recruited through prolific (prolific.co), and completed the study on the Gorilla platform [www.gorilla.sc;
Anwyl-Irvine2020]. The sample size was based off a previous experiment (Geller et al. (2020), Experiment 1), wherein they calculated power to detect a medium sized interaction effect (d = 0.35) using a similar design to the current study. After data collection had ended we had a total of 231 participants. Participants completed the experiment in return for U.S.\$8.00 an hour.

Materials

Stimuli were 188 single-word nouns taken from Geller et al. (2018). All words were from the English Lexicon Project database (Balota et al., 2007). Both word frequency (all words were high frequency; mean log HAL frequency = 9.2) and length (all words were four letters) were controlled. The full set of stimuli can be found at https://osf.io/dsxrc/.

$oldsymbol{Design}$

Per our pre-registration, d', JOLs, and study times were analyzed with a 2

(Typeface: Arial vs. Sans Forgetica) x 2 (Testing Expectancy: High vs. Low) mixed

analysis of variance (ANOVA).

30 Procedure

Similar to Geller et al. (2020) (Experiment 3), four lists (94 words each; 47 in each 131 typeface condition) were used to create the stimuli for a total of 188 words. Ninety-four 132 words from the two of the lists were presented in both the study and test phases and were 133 consider "old", while the 94 words from the other two lists were presented only in the test 134 phase and were considered "new." Words were counterbalanced across the typeface and 135 study/test conditions, such that each word served equally often as a target and a foil in 136 both typefaces across participants. The four word lists were counterbalanced across 137 participants, so that each list was assigned to each role (old/new, Arial/Sans Forgetica) an 138 equal number of times. Word order was completely randomized, such that Arial and Sans 139 Forgetica words were randomly intermixed in the study phase, and Arial and Sans 140 Forgetica old and new words were randomly intermixed in the test phase, with old words 141 always presented in the same typeface at test as they were at study.

The main difference between the current experiment and Geller et al. (2020)

(Experiment 3) is that participants were randomly assigned to one of two conditions: the

high expectancy test condition or the low expectancy test condition. Interested readers can

view the entire task including instructions for each condition by following these links (High

Test Expectancy experiment https://gorilla.sc/openmaterials/72765; Low test expectancy

experiment: https://gorilla.sc/openmaterials/116227).

The experiment proper consisted of four phases: a study phase, JOL phase,
distractor phase, and test phase. During the study phase, a fixation cross appeared at the
center of the screen for 500 ms. The fixation cross was immediately replaced by a word in
teh same location. To continue to the next trial, participants pressed the continue button
at the bottom of the screen. Each trial was self-paced. In the JOLs phase, participants
provided list-wide JOls which required them to denote on a scale of 0-100 how likely it will
be that they will recall the words studied in Arial and Sans Forgetica on a final test. In the

distractor phase, participants completed a short three-minute distractor task wherein they 156 wrote down as many U.S. state capitals as they could. In the test phase, participants took 157 a yes/no recognition memory test. During the test phase, a word appeared in the center of 158 the screen that either had been presented during study ("old") or had not been presented 159 during study ("new"). Old words occurred in their original typeface, and following the 160 counterbalancing procedure, each new word was presented in Arial typeface or Sans 161 Forgetica typeface. For each word presented, participants chose from one of two boxes 162 displayed on the screen: a box labeled "old" to indicate that they had studied the word 163 during study, and a box labeled "new" to indicate they did not remember studying the 164 word. Sans Forgetica Words stayed on the screen until participants gave an "old" or "new" 165 response. All words were individually randomized for each participant during both the 166 study and test phases. After the experiment, participants were debriefed.

68 Results and Discussion

A variation of Cohen's d (d_{avg}) and generalized eta-squared (η_g^2) ; ???) are used as 169 effect size measures. Alongside traditional analyses that utilize null hypothesis significance 170 testing (NHST), we also report the Bayes factors (BFs) for reported null effects. A Bayes 171 Factor > = 3 will be deemed as moderate evidence for null; BF > = 10 strong evidence for 172 the null. All data were analyzed in R (vers. 4.0.2; R Core Team, 2020), with models fit 173 using the afex (vers. 0.27-2; Singmann et al. (2020)) and BayesFactor packages (vers. 174 0.9.12-4.2; Morey and Rouder (2018a)). All figures were generated using ggplot2 (vers. 175 3.3.0; Wickham, 2006). 176

$_{\scriptscriptstyle 77}$ $Recognition \ Memory$

Performance was examined with d', a memory sensitivity measure derived from signal detection theory (Macmillan & Creelman, 2005). The proportions of "old" responses for old/new items are displayed in Fig. 1. Hits or false alarms at ceiling or floor were

changed to .99 or .01. Sensitivity (d') values be seen in Figure 2a. The analysis revealed 181 that when told about a memory test, participants had better discriminatory ability than 182 those not told about a memory test (0.88 vs. 0.72), M $_{\mathrm{diff}}=$ 0.16, F(1, 229) = 4.11, $\eta_g^2=$ 183 .014, p = .044. Individuals were better at discriminating target words presented in Sans 184 Forgetica than Arial (0.86 vs. 0.74), M $_{\rm diff}$ = 0.12, $F(1,\,229)$ = 10.73, η_g^2 =.010, p = .001. 185 This was qualified by an interaction between Test Expectancy and Typeface, F(1, 229) =186 4.34, $\eta_g^2 = .004$, p = .038. Simple effects showed that individuals in the low expectancy 187 group showed better recognition memory for words presented in Sans Forgetica font 188 compared to Arial, F(1, 229) = 14.297, p < .001, $d_{avg} = 0.31$. In the high test expectancy 189 group, there were no differences between the two typefaces, F(1, 229) = 0.716, p = .398, 190 $d_{\text{avg}} = 0.07, \, \text{BF}_{\text{O}1} = 5.83.$ 191

192 **JOLs**

Seven participants did not provide JOls to each typeface. We did not analyze the data for those participants. Using the same model as above, participants in the high testing expectancy group had higher JOLs than those in the low testing group (), F(1,221) = 16.01, $\eta_g^2 = .065$, p < .001. Arial elicited higher JOls than Sans Forgetica (61.5 vs. 57.5), $M_{\text{diff}} = 4.0$, F(1,221) = 27.05, $\eta_g^2 = .004$, p < .001. There was no interaction between Testing Expectancy and Typeface, F(1,221) = 0.13, $\eta_g^2 < .001$, p = .715. Compared to a main effects-only model, there was strong evidence for no interaction, BF₀₁ = 7.28.

200 Study Times

Although not pre-registered, study times less than 200 ms and reaction times greater than 2.5 SD above the mean per condition for each participant were removed. This outlier procedure removed $\sim 3\%$ of the data. Given the heavy positive skew of the data, we log transformed study times to better approximate a normal distribution (see Fig.1C). Evidence for testing expectancy effects on log-transformed study times were inconclusive, F(1,229) =

1.97, $\eta_g^2 = .008$, p = .162, BF = 1.822. Typeface did influence study times: study times were slower for Sans Forgetica than Arial, F(1,229) = 30.91, $\eta_g^2 = .001$, p < .001. There was no interaction between Testing Expectancy and Typeface, F(1,229) = 1.10, $\eta_g^2 < .001$, p = .296. Compared to a main effects-only model, there was strong evidence that there was no interaction between Testing Expectancy and Typeface, BF₀₁ = 5.25.

As predicted, memory sensitivity for Sans Forgetica was higher when testing 211 expectancy was low, but not when testing expectancy was high. This suggests that one 212 potential reason for Taylor et al. (2020) and Geller et al. (2020) failing to find a Sans 213 Forgetica effect was high test expectancy. This finding replicates what Geller and Still 214 (2018) found with a masking perceptual disfluency manipulation. We also found that 215 participants gave lower JOLs to stimuli studied in the Sans Forgetica typeface. These 216 findings are inconsistent with the predictions pre-registered, and contradict the findings of 217 Geller et al. (2020) (Experiment 2) and Taylor et al. (2020) (Experiment 1). One reason 218 for this is that in the current experiment, we used a within-subject manipulation of 219 typeface whereas Geller et al. (2020) (Experiment 2) and Taylor et al. (2020) (Experiment 220 1) used a between-subjects typeface manipulation. The finding of lower JOls to disfluent 221 stimuli compared to more fluent stimuli is inline with other studies using a within-participant manipulation of fluency (Besken and Mulligan (2013); Geller et al. 223 (2018); Rhodes and Castel (2008); Rhodes and Castel (2009) Besken and Mulligan (2013)). In relation to study times, we found that participants studied Sans Forgetica stimuli longer 225 than Arial, regardless of test expectancy. This contradicts the null finding of Geller et al. 226 (2020) (Experiment 3). It is important to note, however, that the examination of study 227 times in Geller et al. (2020) were unplanned, and purely exploratory, making it hard to 228 draw firm conclusions about the effect fo Sans Forgetica on study times. 229

In Experiment 2, we attempt to replicate these findings using a different criterion test: cued recall. Taylor et al. (2020) failed to find a Sans Forgetica effect using highly related cue-target pairs. However, participants were told about the upcoming test. Using

Taylor et al. (2020)'s stimuli we we examined cued recall accuracy with low testing expectany, along with JOLs and RTs.

Experiment 2

Methods

235

237 Participants

One hundred and sixteen participants (N=116) participated through Prolific (Prolific.co), and comleted the study through Gorilla (Anwyl-Irvine et al., 2020). A sensitivity analysis conducted with the R package pwr (Champely, 2020) indicated that our sample size provided 90% power to detect a small effect size (d=0.16) or larger.

$_{ ext{\tiny 242}}$ Design

Cued recall accuracy, JOLs, and reading times to Typefaces (Sans Forgetica vs. Arial) were analyzed with a paired t-test.

$_{245}$ $Materials \ and \ Procedure$

The materials were adopted from Taylor et al. (2020, Experiment 2). Twenty highly associated word pairs were used (see osf page for stimuli characteristics).

The entire experiment can be run by following the following link:

https://gorilla.sc/openmaterials/116224. During the study phase, participants were

presented with a series of 20 word pairs, presented one at time. They were not told about

the upcoming memory test and were told to simply read the cue-target pairs. Participants

were told to press the continue button after they had read each word. Half of the word pairs

were presented in Sans Forgetica and half in Arial. We created two versions of the word

pair list, so that each cue-target pair was presented in each typeface across participants.

All counterbalanced lists contained the same word pairs. In the JOL phase, participants
made list-wide JOLs.In the distractor Phase, participants took part in the same distractor
task as Experiment 1. Finally, in the test phase of the experiment, participants' memory
for the word pairs was tested by presenting the first word of the pair they studied during
phase 1 and asking them to type the second word of that pair into a box. We presented the
memory test in a font not tied to the stud phase so as not to reinstate context at test. The
cued words presented during Phase 1 were presented one-by-one, in a random order.

262 Scoring

To score typed responses during the cued recall phase, we used the lrd package in R (Nicholas P. Maxwell, 2020). The lrd package provides an automated way to score word responses. A partial match of 80% was used to determine whether a typed response was correct or not.

267 Results and Discussion

268 Cued Recall

With low testing expectancy, performance was better when words were presented in Sans Forgetica (47% vs. 42%), $M_{\rm diff}=5\%$, t(115)=2.363, SE=0.046, p=.020, 95 CI% [0.008, 0.090], $d_{\rm avg}=0.18$. See fig 2a.

272 **JOLs**

The analysis of JOls revealed that Partcipants' JOLs were lower for Sans Forgetica than Arail (65.83 vs. 70.84), $M_{\rm diff}=$ -5.02, t(108)= -3.12, SE= 1.61, 95 CI% [0.030, 0.114], $p=.002,\ d_{\rm avg}=$ 0.15. See fig 2a.

$Reaction \ Times$

287

Similar to Experiment 1, we excluded reaction times less than 200 ms and reaction 277 times greater than 2.5 SD above the mean per condition for each participant. The outlier procedure removed $\sim 3\%$ of the data. We also log transformed the data (see Fig.1C for reaction time data). An analysis of study time using a paired t-test on mean log RTs 280 revleaved that study times were longer for Sans Forgetica than Arial (7.58 vs. 7.51), $M_{\rm diff}$ 281 = 0.072, t = 3.40, SE = 236, p < .001, 95 CI% [0.030, 0.114], $d_{\rm avg}$ = 0.13. 282 Using a cued recall test, we have again showed that if test expectancy is low, Sans 283 Forgetica can constitue a desirable difficulty. We obersved a 5% increase when participants 284 studied cue-target pairs in Sans Forgetica. Further, we also showed that again Sans 285 Forgetica produced lower JOIs and leads to longer study times. 286

General Discussion

The present experiments focused on examining whether testing expectancy serves as 288 boundary condition to the Sans Forgetica effect. Specifically, it was assumed that if Sans 289 Forgetica is a desirable difficulty, it fosters learning by increasing mental effort and by 290 stimulating deeper processing - but only when students are endangered to process 291 materials superficially. When students study in preparation for an upcoming test(high test 292 expectancy), they invest mental effort and take their time to elaborate on all context, 293 regardless of whether the to-be-learned information is fluent or disfluent. However, when 294 students do not expect a test (low test expectancy), they might choose to study the text 295 they deem more difficult (e.g., see the discrepancy-reduction model, (???)]. This would 296 lead to a desirable effect of Sans Forgetica on memory. 297

In line with this prediction, Experiment 1, using a yes/no recognition memory test, revealed a desirable effect of Sans Forgetica only when participants were not told about an upcoming memory test. Further, In Experiment 2, using a low testing expectancy design, 304

cued recall performance was significantly higher for Sans Forgetica than Arial. 301 Furthermore, in both experiments Sans Forgetica produced lower JOLs and longer study 302 times overall thereby suggesting that Sans Forgetica is perceptually disfluent (see ??? 303 evidence for this with eve-tracking evidence).

While it might be tempting to use this as evidence for the use of Sans Forgetica as 305 study tool, the current findings need to be interpreted with caution. First, and most 306 importantly, the finding that Sans Forgetica is only beneficial to memory under low test 307 expectancy makes its use in the educational domain impractical. Students always know about upcoming tests. Second, looking at the mnemonic effect sizes of the Sans Forgetica effect (Experiment 1: d = 0.30; Experiment 2: d = .25), the effects are quite small in nature. It is unclear if these effects would replicate in an educational setting where effect 311 sizes are a known to be a lot smaller (Butler et al., 2014). 312

Conclusion 313

Recent new reports have recommended that teachers and students use perceptual 314 disfluency to enhance learning. Although we have shown that Sans Forgetica can enhance 315 learning in a very simplified context (i.e., list learning), its efficaciousness as a potential 316 learning technique is tempered by the finding that testing expectancy can eradicate the 317 effect. In an educational setting, students are always told about upcoming tests. Thus, 318 Sans Forgetica, and perceptual disfluency in general, might not be an effective 319 manipulation to enhance memory in a more ecologically valid setting. What is clear from 320 the current findings is that the impact of perceptual disfluency manipulations, such as Sans 321 Forgetica, on memory is straightforward. Future research should continue to explore the boundary conditions of the disfluency.

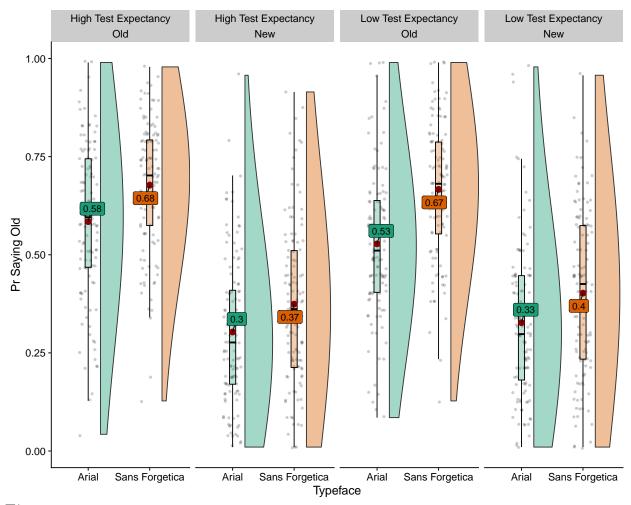

Figure 1
Raincloud plots (Allen et al., 2019) depicting raw data (dots), box plots, and half violin kernel desntiy plots, with mean (red dot). Proportion of "old" responses as a function of Test Expectancy for Experiment 1.

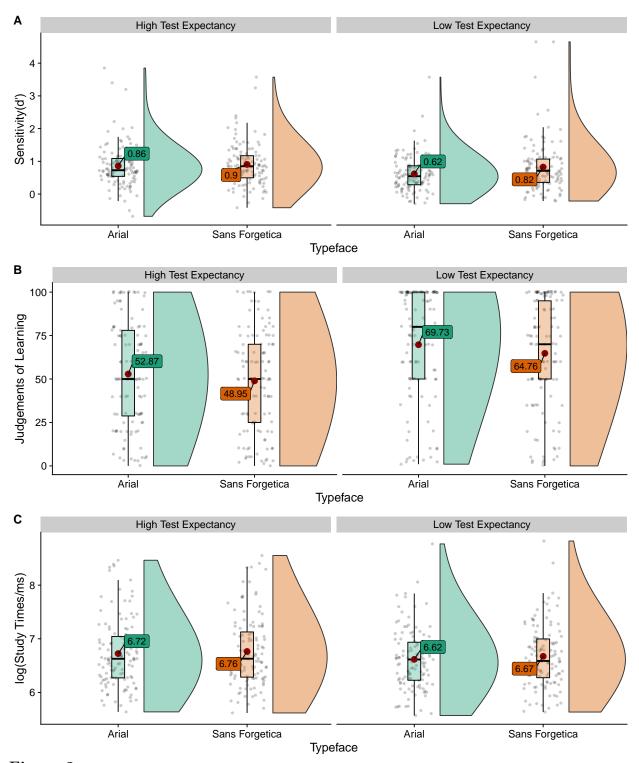

Figure 2

Raincloud plots (Allen et al., 2019) depicting raw data (dots), box plots, and half violin kernel desntiy plots. A. Memory sensitivity (d') as a function of Typeface and Testing Expectancy.

B. Judgements of Learning as a function of Typeface and Test Expectany. C. Study times (log transformed) as a function of Typeface and Test Expextancy. Raincloud plots (Allen et al., 2019) depicting raw data (dots), box plots, and half violin kernel Violin plots represent the kernal density of avearge accuracy (black dots) with the mean (white dot)

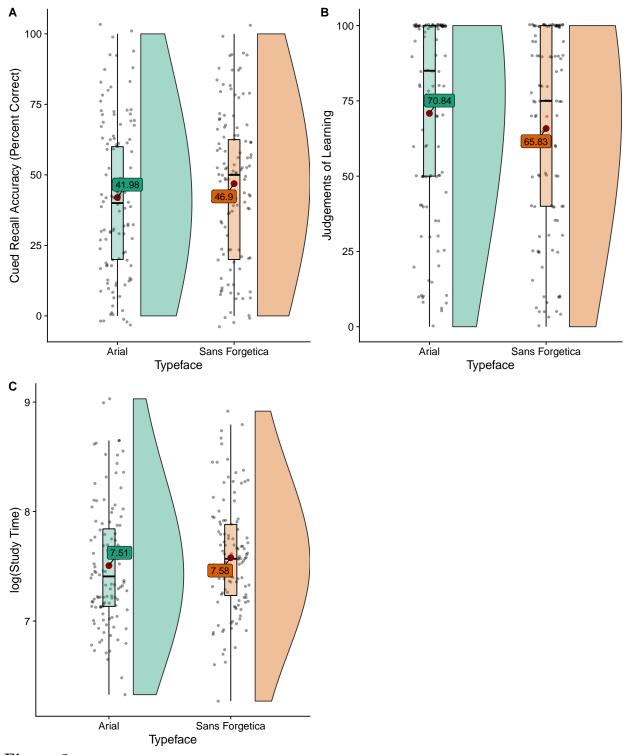

Figure 3

Raincloud plots (Allen et al., 2019) depicting raw data (dots), box plots, and half violin kernel desntiy plots. A. Memory sensitivity (d') as a function of Typeface and Testing Expectancy.

B. Judgements of Learning as a function of Typeface and Test Expectany. C. Study times (log transformed) as a function of Typeface and Test Expextancy. Raincloud plots (Allen et al., 2019) depicting raw data (dots), box plots, and half violin kernel Violin plots represent the kernal density of avearge accuracy (black dots) with the mean (white dot)
